We have been developing a gas-jet transport system coupled to GARIS as a novel technique for superheavy element chemistry.¹⁾ So far, isotopes of element 104, ^{261}Rf , and element 106, ^{265}Sg , have been produced for chemical studies in the $^{248}\text{Cm}(^{18}\text{O},5n)$ and $^{248}\text{Cm}(^{22}\text{Ne},5n)$ reactions, respectively.^{1,2)} In this work, we produced element 105, ^{262}Db in the $^{248}\text{Cm}(^{19}\text{F},5n)$ reaction and investigated its decay properties in detail for future chemical studies of Db.

$^{248}\text{Cm}_2\text{O}_3$ targets with thicknesses of 230, 290, and 330 $\mu\text{g cm}^{-2}$ were prepared by electrodeposition onto a 2- μm Ti foil. The $^{19}\text{F}^{6+}$ or $^{19}\text{F}^{9+}$ ion beam was extracted from RILAC. The beam energies were 103.1 and 97.4 MeV at the middle of the target, and the typical beam intensity was 4 particle μA . The evaporation residues (ERs) separated by GARIS were guided into the gas-jet chamber through a 0.5- μm -thick Mylar window, which was supported by a grid with 84% transparency. Several magnetic rigidities were investigated in $B\rho = 1.73\text{--}2.09$ Tm at a He pressure of 33 Pa; the optimal collection efficiency for ^{262}Db was $8.1 \pm 2.2\%$ at $B\rho = 1.89$ Tm. The ERs were then transported by a He/KCl gas jet to the rotating-wheel apparatus MANON for α /SF spectrometry. In MANON, aerosol particles were deposited on a Mylar foil of 0.5- μm thickness, 40 of which were set on the periphery of a rotating wheel. The wheel was stepped at 15.5 s intervals to position the samples between 15 pairs of Si PIN photodiodes.

We searched for time-correlated $\alpha_1\text{--}\alpha_2$ event pairs in the time window of 58.5 s and in the energy range of 8.0 MeV $\leq E_\alpha \leq 9.0$ MeV. As a result, 71 and 4 $\alpha_1\text{--}\alpha_2$ pairs were found at 103.1 and 97.4 MeV, respectively. By referring to the α -particle energies (E_α) and half-lives ($T_{1/2}$) adopted for ^{262}Db and its daughter ^{258}Lr ,³⁾ 74 $\alpha_1\text{--}\alpha_2$ were reasonably assigned to $^{262}\text{Db} \rightarrow ^{258}\text{Lr} \rightarrow$. One exceptional $\alpha_1\text{--}\alpha_2$ pair at 103.1 MeV was $^{261}\text{Db} \rightarrow ^{257}\text{Lr} \rightarrow$ via the $^{248}\text{Cm}(^{19}\text{F},6n)$ reaction. No $\alpha_1\text{--}\alpha_2$ pair on ^{263}Db produced in the $^{248}\text{Cm}(^{19}\text{F},4n)$ reaction ($^{263}\text{Db} \rightarrow ^{259}\text{Lr} \rightarrow$) was observed. We also observed two SF events that correlated with the α decays with energies and decay times of ^{262}Db . This suggests that small SF and/or EC branches exist in ^{258}Lr ; the

EC decay daughter of ^{258}Lr , ^{258}No , is a short-lived SF decaying nuclide with $T_{1/2} \approx 1.2$ ms and $b_{\text{SF}} = 100\%$.³⁾ On the basis of the semi-empirical systematics of nuclear mass and half-lives, the EC decay would be favored in ^{258}Lr next to the α decay.⁴⁾

The observed decay patterns of ^{262}Db and ^{258}Lr are shown in Fig. 1. The α -particle energies of $E_\alpha = 8.46 \pm 0.04$ (α intensity $I_\alpha = 70 \pm 5\%$) and 8.68 ± 0.03 MeV ($30 \pm 5\%$) were determined for ^{262}Db , though three energies of $E_\alpha = 8.45$ (75%), 8.53 (16%), and 8.67 (9%) had been adopted.³⁾ The half-life of ^{262}Db was measured to be $T_{1/2} = 33.8^{+4.4}_{-3.5}$ s, and this agrees well with $T_{1/2} = 34 \pm 4$ s in Ref.³⁾ In this work, the SF activity with $T_{1/2} = 30.2 \pm 6.1$ s was also assigned to ^{262}Db with a SF branch of $b_{\text{SF}} = 52 \pm 4\%$. This is larger than the currently adopted $b_{\text{SF}} \sim 33\%$.³⁾ On the other hand, the α -particle energies of ^{258}Lr range from $E_\alpha = 8.43$ to 8.73 MeV and the average α energy of $E_\alpha = 8.61$ MeV agrees well with $E_\alpha = 8.605$ MeV deduced from the α energies and intensities of ^{258}Lr in Ref.³⁾ The half-life of ^{258}Lr , $T_{1/2} = 3.54^{+0.46}_{-0.36}$ s also agrees with that in Ref.³⁾ ($T_{1/2} = 3.9^{+0.4}_{-0.3}$ s). The EC branch in ^{258}Lr was first determined to be $b_{\text{EC}} = 2.6 \pm 1.8\%$. The cross sections for the $^{248}\text{Cm}(^{19}\text{F},5n)^{262}\text{Db}$ reaction were 2.1 ± 0.7 nb at 103.1 MeV and $0.23^{+0.18}_{-0.11}$ nb at 97.4 MeV, while those for the $^{248}\text{Cm}(^{19}\text{F},4n)^{263}\text{Db}$ reaction were the upper limits of ≤ 0.064 nb at 103.1 MeV and ≤ 0.13 nb at 97.4 MeV.

Fig. 1. Observed decay patterns for the chain $^{262}\text{Db} \rightarrow ^{258}\text{Lr} \rightarrow ^{258}\text{No}$. The α -particle energies and intensities (I_α) of ^{258}Lr and all decay data of ^{258}No are taken from Ref.³⁾
