Shape evolution in neutron-rich nuclei with the neutron number $N>82$ and the proton number $Z>50$ beyond the doubly magic ${ }^{132} \mathrm{Sn}$ nucleus have been investigated along several isotopic chains. The EURICA project ${ }^{1)}$ provides us with an opportunity to study extremely neutron-rich nuclei using $\beta$-decay and isomer-decay spectroscopy. We reported the results of the isomer-search experiment for neutron-rich Cs isotopes ${ }^{2)}$, where new isomers were found in ${ }^{145} \mathrm{Cs},{ }^{146} \mathrm{Cs}$, ${ }^{147} \mathrm{Cs}$, and ${ }^{148} \mathrm{Cs}$. To understand the nuclear structure of these neutron-rich Cs isotopes in the low-spin states, we studied the $\beta$ decay of neutron-rich Xe to Cs isotopes.

The neutron-rich Xe isotopes were produced through in-flight fission reaction using a $345-\mathrm{MeV} /$ nucleon ${ }^{238} \mathrm{U}$ beam. Particle identification was performed using the mass-to-charge ratio $(A / Q)$ and the atomic number deduced from the information of time-of-flight (TOF), magnetic rigidity $(B \rho)$ and energy loss of fission fragments through BigRIPS and ZeroDegree Spectrometer ${ }^{3)}$. The isotopes were implanted into a stack of five double-sided Si-strip detectors $(W A S 3 A B i)^{1)}$. $\beta$ rays emitted from the isotopes were also detected by WAS3ABi. The parent nuclei of the $\beta$ decay were identified by position correlation on the WAS3ABi between the implanted fragments and the detected $\beta$ rays. $\gamma$ rays emitted after the $\beta$ decay were detected by the $\gamma$-ray detector array which is called EURICA ${ }^{1)}$.

[^0]

Fig. 1. $A / Q$ spectrum of neutron-rich Xe isotopes.
Figure 1 shows a spectrum of particle identification for the $\mathrm{Xe}(Z=54)$ isotopes as a function of $A / Q$. The fully-stripped ${ }^{A} \mathrm{Xe}^{54+}$ ions are separated from the hydrogen-like ${ }^{A-3} \mathrm{Xe}^{53+}$ ones owing to the high $A / Q$ resolution.

Coincidence data of $\beta-\gamma$ and $\beta-\gamma-\gamma$ with particle identification of ${ }^{143} \mathrm{Xe},{ }^{144} \mathrm{Xe},{ }^{145} \mathrm{Xe},{ }^{146} \mathrm{Xe}$, and ${ }^{147} \mathrm{Xe}$ isotopes is analyzed. As an example, the $\gamma$-ray energy spectrum and the decay curve for the $\beta$ decay of ${ }^{145} \mathrm{Xe}$ to ${ }^{145} \mathrm{Cs}$ are shown in Fig. 2. We found 11 new $\gamma$ rays associated to the transitions in ${ }^{145} \mathrm{Cs}$ emitted after the $\beta$ decay of ${ }^{145} \mathrm{Xe}$. These $\gamma$-ray peaks are represented as full circles in Fig. 2. Other peaks are mostly assigned to transitions in the granddaughter ${ }^{145} \mathrm{Ba}$ nucleus. The inset in Fig. 2 shows the decay curve deduced by the time difference between the implantation of ${ }^{145} \mathrm{Xe}$ and the detection of the $\beta$ rays gated on newly found 5 $\gamma$ rays in ${ }^{145} \mathrm{Cs}$. The half-life of the $\beta$ decay was determined to be $197(10) \mathrm{ms}$, which is consistent with the reported one in Ref. 4. Detailed analyses are in progress.

Fig. 2. $\gamma$-ray energy spectrum and decay curve of the $\beta$ decay of ${ }^{145} \mathrm{Xe}$ to ${ }^{145} \mathrm{Cs}$.
